

Your approved candidate says who the product is for and what it does. That is a set of requirements, and it leaves things out. This is where you start working out who you need to gather requirements from and what you most need to find out. Using your evidence from Discussion 05:

1. Your requirements. List what your product must do, as your team understands it today. One line each.

R1 - The user can upload an audio file (MP3, WAV)

R2 - The user can upload a video file (MP4, MOV)

R3 - The system converts the speech in an uploaded file into a text transcript

R4 - The user can see job status for each upload

R5 - The user can export the transcript (TXT, DOCX, PDF)

R6 - The user can see a list of their past transcripts

R7 - The user has an account and only they can see their own files and transcripts

2. Who has a stake. List the groups with a stake in your product other than the people who use it. For each, say what they could want from it. (Discussion 05, Q1 and Q3)

Dr. Bowman - Want us to succeed and fulfill his expectations of the project in its entirety

AI Provider - Needs to maintain compliance and prevent abuse of the API.

Media Owner - Whoever owns/is present in the media being transformed has a stake in they may prioritize privacy.

The Team: We would want a buildable scope, maintainable code, and tools that we already know how to use.

3. What is missing? Criticize your list for what it leaves unstated. Include the qualities nobody asks for by name, such as security, performance and reliability. (Discussion 05, Q4)

Performance - most people would want this service to be fast, this would also affect the max file size and concurrent jobs.

Accuracy - what accuracy do users expect on different kinds of audio and what would they do when it is wrong.

Privacy - do we just store the transcript once it is done or do we also store the original media

Reliability - If an upload fails or the transcription fails, is there functionality to resume in the middle

Security - The user accounts and information tied to those accounts needs to be kept securely. As well as this, the entire hosting platform needs to be secure.

4. What it would cost. Rank what is missing by what it would cost to find out late. For the top three, say what finding out late would cost your team. (Discussion 05, Q4)

1. Hosting and processing cost - If we find this out too late, then it would make our project a no-go because it costs too much to bring the functionality that we are wanting to implement.

2. Accuracy targets not being met - If accuracy remains low with the chosen engine that we use, this would make the product less effective at its job. If we were to switch to a new engine, this could cost us time to reintegrate a new speech recognition system.
3. Privacy - If users expect media is not stored, then that could rule out some cloud APIs.
4. Cost of processing large files - This would cost our team some functionality because we might need to limit the size of the files which would reduce the usefulness of our project.
5. Security - having weak security would be bad to find out late as this could leave the service open to attacks.

5. Who you will not ask. Name at least one group your product affects that your team does not intend to consult. Say why, and what you risk by not asking. (Discussion 05, Q5)

People present in media submitted, as we cannot reach out to them beforehand when the user submits the media. Transforming without consent could be an issue that we can't solve by directly asking.
